What is a global load in a wind turbine?

When discussing blade loads, most of the time the so-called global loads are of primary interest. The global loads are the loads that are transferred from the blade into the hub/main shaft assembly, being the next main component along the load path from the rotor to the foundation of a wind turbine.

What are the major loading conditions applied to a wind turbine blade?

The major loading conditions applied to the blade are not static. Fatigue loading can occur when a blade is exceeded. It is possible to produce a wind turbine blade capable of operating within the fatigue limit of its materials. However, such a design would require excessive amounts of structural material.

What is a structural load analysis of a wind turbine blade?

Structural Load Analysis Modern load analysis of a wind turbine blade would typically consist of a three dimensional CAD model analysed using the Finite Element Method. Certification bodies support this method and conclude that there is a range of commercial software available with accurate results.

What are the aerodynamic design principles for a wind turbine blade?

The aerodynamic design principles for a modern wind turbine blade are detailed, including blade plan shape/quantity, aerofoil selection and optimal attack angles. A detailed review of design loads on wind turbine blades is offered, describing aerodynamic, gravitational, centrifugal, gyroscopic and operational conditions.

## 1. Introduction

What are the dynamic equations for wind turbine blade & generator?

The dynamic equations for the wind turbine blade and generator are expressed as follows: (23)  $J \ddot{\theta} + D \dot{\theta} = T_a - k_r \theta - T_l$  (24)  $J_g \ddot{\phi} = T_h - k_g \phi - T_e$  The gear ratio for the transmission system is given by (25)  $n_g = \omega_g / \omega_r = T_l / T_h$

How does a wind turbine blade work?

The blade is made capable of supporting these loads by the inclusion of a spar that runs the length of the blade (beginning at the first reference airfoil). In practice, many wind turbines actually incorporate two spars, placed (very roughly estimated) at 33% and 67% of chord.
